It is a basic Java utility, which, with the help of the Java code, provides a simple functionality of evaluating, analyzing and generating the results for a few simple queries. The Query Analyzer is divided into four modules: The first module handles user data, and presents a window where you can enter information about the query to be analyzed. When you complete the window, you submit the query. The second module displays the results of the query. The third module analyzes the query to provide you with the results. Finally, the fourth module provides you with some useful information about the query. The structure of the Query Analyzer is as follows: User Data Window The Query Analyzer is divided into 4 main parts. The first is the "User Data" Window, where you can enter the query. The second part is a window where you can enter data about the query. The third window displays the results. Finally, the fourth window provides you with information about the query, as well as the process you used to create the query. You can change the general display of the module by editing the following files: How to use Query Analyzer: STEP 1: Select Query Analyzer from the "Tools" menu. Oracle Database Administration is a set of hands-on skills to get you started on the job search, or to prepare yourself for a management position at a large, medium or small enterprise. A large portion of the database systems management work is related to system administration. This book is designed to teach you the principles of system administration. System administration consists of managing and administering server and workstation hardware and software. This book begins by teaching you how to work with operating system command line interfaces. You will be introduced to how to configure and manage the operating system. This book presents you the commands used to manage database systems. It starts by explaining the basic database features and features available in Oracle. You will learn about the basics of database management system including database architecture, table, database design, views and table spaces. It will teach you how to administer the users, security, database connection pooling, XA transactions, JDBC API, setting the database memory and working with Oracle SQL*Plus. This book will teach you how to administer the Oracle Database itself, backing up, restoring, tuning, databases file allocation, aits and so on. This book covers the database administration skills and knowledge that are required for the Oracle Database System Administrator and Oracle Database Developer. This book shows the key skills and knowledge required in a database administrator. There are various parts of the book. Each of these parts has a separate objective in the book. Query Analyzer is a tool designed to help you analyze the performance of your database queries. It's a standalone application and it does not require any external DLLs or command-line executables. Query Analyzer supports several native databases and also allows you to convert your data to native queries of your choice. Features: - Support different platforms (like Windows, Linux and Unix) - Ability to convert queries to native code (JDBC, ODBC, ODBC/JDBC, ADO.NET) - Exact, relative and dictionary analysis of queries - Ability to analyze your queries over given periods of time - Several database analyzers - Ability to send queries to the SQL Profiler Usage: You need to extract the database logs. To do that, you will need to run a command-line tool like sysmon (a free Windows utility), into "Detail" or "Summary" mode (depending on your needs) and extract the generated log file. You can also extract the data from the saved logs to a text file by using the exported tool. For detailed instructions, please visit: Programmatic methods The following routines are supported by this project: Dictionary attack Dictionary attack generates a list of words that are present in your database and in your user dictionary. The attack uses multiple heuristics that are each evaluated on a set of words. Dictionary attack is more accurate than a direct query on your user dictionary. But still, it can be defeated by using heuristics. So, your goal should be to make the application as difficult to defeat as possible. Dictionary attack returns a list of the SQL queries, which can be inserted into your users dictionary. Summary attack Summary attack is used to detect the most frequent queries issued by your users. Summary attack returns a list of the SQL queries, which can be inserted into your users dictionary. Exact match attack Exact match attack uses a simple heuristic that matches the entire query with a user-defined string. The heuristic is not meant to defeat the attack. It is recommended to provide a better match string, because it will speed up the attack. Exact match attack can be defeated by using a tokenizer. Relative match attack Relative match attack uses a relatively simple heuristic. It analyzes the statistics of the matched queries in order to return a list of similar queries. The attack is defeated by using a tokenizer. Tokenizer Tokenizer is used to convert a string into an array of tokens, which can be used to break it into smaller and smaller

chunks. Tokenizer is quite easy to defeat (for a human) because a human can recognize single
